## Introduction

Neutrinos are one of the elementary particles we currently know and are included in the Standard Model (SM). However, some properties of neutrinos can not be described by the SM, which shows clues of the new physics beyond the SM.

SNO+ is a multi-purpose neutrino experiment

SNO+ experiment is planned to explore one of the unknown properties of neutrinos: whether the neutrinos are Majorana particles or Dirac particles.

In this thesis, a position and time reconstruction algorithm is developed for SNO+ physics phases.

### 1.1 Studies on Solar Neutrinos: History and Current Status

## Chapter 2

# Neutrino physics

### 2.1 Neutrino Flavor Transformation and Oscillation

Neutrino oscillation was first discovered in 1998. It is the first direct evidence showing that the Standard Model is incomplete.

The neutrinos generated with definite flavor from weak interactions and related to solar neutrino oscillations

#### 2.1.1 Vacuum Oscillation

#### 2.1.2 Matter Effect

The matter effect is caused by neutrinos interacting with ambient electrons and nucleons in matter such as the Sun or the Earth.  $\nu_e$  interacts with electrons via both charged weak current (exchanging  $W$  boson) and neutral weak current ( $Z$  boson) while  $\nu_\mu$  and  $\nu_\tau$  interact only by the neutral current. The  $\nu_e$  energy has an addition term,  $V_{CC} = \sqrt{2}G_F n_e$ , where  $n_e$  is the number density of the electrons in matter and  $G_F$  is the Fermi coupling constant for the weak interaction. This affects the oscillation probabilities for neutrinos propagating in matter compared to vacuum, which is called the Mikheyev-Smirnov-Wolfenstein (MSW) mechanism[43, 42].

In vacuum two-flavor mixing, the Schrödinger equation can be written (in natural

units)[49]:

$$i \frac{d}{dt} \begin{bmatrix} \nu_e \\ \nu_\mu \end{bmatrix} = H_0^f \begin{bmatrix} \nu_e \\ \nu_\mu \end{bmatrix}, \quad (2.1)$$

where

$$\begin{aligned} H_0^f = \frac{1}{2E} & \begin{bmatrix} m_1^2 \cos^2 \theta + m_2^2 \sin^2 \theta & (m_2^2 - m_1^2) \sin \theta \cos \theta \\ (m_2^2 - m_1^2) \sin \theta \cos \theta & m_1^2 \sin 2\theta + m_2^2 \cos^2 \theta \end{bmatrix} = \\ & \frac{\Delta m_{21}^2}{4E} \begin{bmatrix} -\cos 2\theta & \sin 2\theta \\ \sin 2\theta & \cos 2\theta \end{bmatrix} + \frac{(m_1^2 + m_2^2)}{4E} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \end{aligned} \quad (2.2)$$

and  $\Delta m_{21}^2 = (m_2^2 - m_1^2)$ .

To simplify the calculation, we can drop the second unitary term of  $H_0^f$  that is irrelevant to the neutrino flavor transformation. Including the matter effect, we obtain:

$$H_m = \begin{bmatrix} -\frac{\Delta m_{21}^2}{4E} \cos 2\theta + \sqrt{2}G_F n_e & \frac{\Delta m_{21}^2}{4E} \sin 2\theta \\ \frac{\Delta m_{21}^2}{4E} \sin 2\theta & \frac{\Delta m_{21}^2}{4E} \cos 2\theta \end{bmatrix} \quad (2.3)$$

We define a mixing angle in matter,  $\theta_m$  as:

$$\tan 2\theta_m = \frac{\Delta m^2 \sin 2\theta}{\Delta m^2 \cos 2\theta - 2\sqrt{2}EG_F n_e}, \quad (2.4)$$

and define an effective squared-mass difference in matter  $\Delta m_m^2$  as:

$$\Delta m_m^2 = \sqrt{(\Delta m^2 \cos 2\theta - 2\sqrt{2}EG_F n_e)^2 + (\Delta m^2 \sin 2\theta)^2}. \quad (2.5)$$

In analogy with mixing in vacuum, we can write the mixing equation relating the energy eigenstates in matter  $(\nu_{1m}, \nu_{2m})$  to the flavor eigenstates with a diagonalized Hamiltonian:

$$\begin{bmatrix} \nu_e \\ \nu_\mu \end{bmatrix} = \begin{bmatrix} \cos \theta_m & \sin \theta_m \\ -\sin \theta_m & \cos \theta_m \end{bmatrix} \begin{bmatrix} \nu_{1m} \\ \nu_{2m} \end{bmatrix}. \quad (2.6)$$

The probability of flavor transformation in matter is:

$$P_{\nu_e \rightarrow \nu_\mu} = \sin^2(2\theta_m) \sin^2 \left( \frac{\Delta m_m^2 L}{4E} \right). \quad (2.7)$$

The denominator in equation (2.4) implies a resonance condition:

$$V(n_e) = \sqrt{2}G_F n_e = \frac{\Delta m^2 \cos 2\theta}{2E}. \quad (2.8)$$

From this condition, for a given  $E$ , there is a resonance density  $n_e^{reson}$  while for a given  $n_e$ , there is a resonance energy  $E^{reson}$ . When the resonance condition is satisfied,  $\theta_m = \frac{\pi}{4}$  and two flavor neutrinos are maximally mixed, even if the vacuum mixing angle  $\theta$  is small. This is called matter enhanced neutrino oscillation[43, 20].

### 2.1.3 Three-flavor Mixing

For three-flavor neutrino mixing, we have[44]:

$$|\nu_f\rangle = \sum_{k=1}^3 U_{fk}^* |\nu_k\rangle, \quad (2.9)$$

where  $f = e, \mu, \tau$  and  $k = 1, 2, 3$ . The unitary PMNS matrix,  $U_{PMNS}$ , can be parametrized as:

$$U_{PMNS} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \theta_{23} & \sin \theta_{23} \\ 0 & -\sin \theta_{23} & \cos \theta_{23} \end{bmatrix} \begin{bmatrix} \cos \theta_{13} & 0 & e^{-i\delta_{CP}} \sin \theta_{13} \\ 0 & 1 & 0 \\ e^{-i\delta_{CP}} \sin \theta_{13} & 0 & \cos \theta_{13} \end{bmatrix} \begin{bmatrix} \cos \theta_{12} & \sin \theta_{12} & 0 \\ -\sin \theta_{12} & \cos \theta_{12} & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (2.10)$$

In the PMNS matrix, we have four parameters: the three mixing angles  $\theta_{12}, \theta_{13}, \theta_{23}$  and the charge-parity (CP) violation parameter of lepton sector,  $\delta_{CP}$ . The unknown value of  $\delta_{CP}$  is related to leptogenesis, the hypothetical physical process that produced an asymmetry between leptons and antileptons in the very early universe[?]. In addition, there are two squared-mass differences,  $\Delta m_{21}^2 = m_2^2 - m_1^2$  and  $\Delta m_{32}^2 = |m_3^2 - m_2^2|$ . The sign of  $\Delta m_{32}^2$  is unknown and it indicates a mass hierarchy problem of whether neutrino mass is normal hierarchy (NH,  $m_3 > m_2 > m_1$ ) or inverted hierarchy (IH,  $m_3 < m_1 < m_2$ )[44].

Currently, these six parameters have been measured by neutrino oscillation experiments. These experiments can be classified by the neutrino sources they use. They are the solar, the reactor, the atmospheric, the accelerator and the astronomical neutrino experiments. Table 2.1 lists the energy scale of the neutrino source as well as the example experiments.

Table 2.1: Oscillation neutrino experiments.

type	source	$E_\nu$	example
solar	the Sun	MeV scale	SNO
reactor	reactor	MeV scale	DayaBay
atmospheric	cosmic-ray	GeV scale	SuperK
accelerator	$\nu$ beam from accelerator	GeV scale	T2K
astronomical	astronomical objects	GeV-EeV scale	IceCube

For the  $\Delta m_{21}^2$  and  $\theta_{12}$ , the combined analysis of the measurements from the reactor experiment KamLAND and SNO gave  $\Delta m_{21}^2 = 7.59_{-0.21}^{+0.21} \times 10^{-5} eV^2$  and  $\tan^2 \theta_{21} = 0.47_{-0.05}^{+0.06}$ [?].

The accelerator neutrino experiments as well as the atmospheric neutrino experiments have measured  $\Delta m_{32}^2$  and  $\theta_{23}$ . The most recent results from SuperK show that in NH,  $\sin^2 \theta_{23} = 0.588_{-0.064}^{+0.031}$  and  $\Delta m_{32}^2 = 2.5_{-0.20}^{+0.13} \times 10^{-3} eV^2$ [?].

In 2012, the reactor neutrino experiment Daya Bay reported the discovery of non-zero  $\theta_{13}$  with a significance of  $5.2\sigma$ . In 2016, Daya Bay reported that  $\sin^2 2\theta_{13} = 0.0841 \pm 0.0027(stat.) \pm 0.0019(syst.)$ . This high-precision result makes  $\sin^2 2\theta_{13}$  the best measured mixing angle[?, ?].

$\delta_{CP}$  is examined by the experiments which measure the difference between neutrino and antineutrino oscillation probabilities  $P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta)$  and  $P(\nu_\alpha \rightarrow \nu_\beta)$ [?]. In 2017, the T2K experiment in Japan rejected the hypothesis that neutrinos and antineutrinos oscillate with the same probability at 95% confidence ( $2\sigma$ ) level. This indicates a hint of CP symmetry broken by neutrinos[?].

The oscillation probability in matter can be written in a concise and exact form as [29]:

$$P(\nu_e \rightarrow \nu_\mu) = A \cos \delta + B \sin \delta + C$$

will also provide the information for the CP- and T-violation by investigating the quantities of:

$$A_{CP} = \frac{P(\nu_\alpha \rightarrow \nu_\beta) - P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta)}{P(\nu_\alpha \rightarrow \nu_\beta) + P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta)}$$

$$A_T = \frac{P(\nu_\alpha \rightarrow \nu_\beta) - P(\bar{\nu}_\beta \rightarrow \bar{\nu}_\alpha)}{P(\nu_\alpha \rightarrow \nu_\beta) + P(\bar{\nu}_\beta \rightarrow \bar{\nu}_\alpha)}$$

## 2.2 Majorana Neutrino

Dirac equation  $(i\gamma^\mu \partial_\mu - m)\psi = 0$ , get coupled equations

The interpretation of the  $0\nu\beta\beta$  process is considered as exchanging light Majorana neutrinos. In this case the effective Majorana mass  $\langle m_{ee} \rangle = \sum_{i=1}^3 |U_{ei}|^2 m_i$  ( $i = 1, 2, 3$ ), where  $U_{ei}$  are the elements of the neutrino mixing matrix for the flavor state  $\nu_e$ , and  $m_i$  are the mass eigenvalues of the mass eigenstates (from (2.9)). The observable quantity is the half-life:

$$(T_{1/2}^{0\nu\beta\beta})^{-1} = G_{PS}(Q, Z)|M_{Nuclear}|^2 \langle m_{ee} \rangle^2,$$

Majorana found a representation of the  $\gamma$ -matrices as follow:

$$\gamma_M^0 = \begin{pmatrix} 0 & \sigma^2 \\ \sigma^2 & 0 \end{pmatrix}, \gamma_M^1 = \begin{pmatrix} \sigma^3 & 0 \\ 0 & \sigma^3 \end{pmatrix}, \gamma_M^2 = \begin{pmatrix} -\sigma^2 & 0 \\ 0 & \sigma^2 \end{pmatrix}, \gamma_M^3 = -i \begin{pmatrix} \sigma^1 & 0 \\ 0 & \sigma^1 \end{pmatrix}$$

These matrices themselves are pure imaginary.

## 2.3 Double Beta Decay

For heavy radioactive isotopes with nuclei of even neutron number ( $N$ ) and even proton number ( $Z$ ) (called even-even nucleus), beta decay will lead to an odd-odd nucleus which is less stable. For some such isotopes the beta decay is energetically forbidden. In 1935, Maria Goeppert-Mayer pointed out that they can still decay through a double beta decay process:  $(Z, A) \rightarrow (Z + 2, A) + 2e^- + 2\bar{\nu}_e + Q_{\beta\beta}$ , where the  $Q_{\beta\beta}$  is the released energy. This is called ordinary double beta decay or  $2\nu\beta\beta$ , which is allowed by the Standard Model and with a typical half-life  $T_{1/2} > 10^{19}$  years[?].

In 1937, Ettore Majorana proposed that neutral spin-1/2 particles (fermions) can be their own antiparticles[?]. If neutrinos have this behaviour, the process called neutrinoless double beta decay ( $0\nu\beta\beta$ ) will also be expected. The Feynman diagrams of  $2\nu\beta\beta$  and  $0\nu\beta\beta$  are illustrated in Figure ??.

The interpretation of the  $0\nu\beta\beta$  process is considered as exchanging light Majorana neutrinos. In this case the effective Majorana mass  $\langle m_{ee} \rangle = \sum_{i=1}^3 |U_{ei}|^2 m_i$  ( $i = 1, 2, 3$ ),  $U_{ei}$  are the elements of the neutrino mixing matrix for the flavor state  $\nu_e$ , and  $m_i$  are the mass eigenvalues of the mass eigenstates (from (2.9)). The observable quantity is the half-life:

$$(T_{1/2}^{0\nu\beta\beta})^{-1} = G_{PS}(Q, Z) |M_{Nuclear}|^2 \langle m_{ee} \rangle^2,$$

where  $G_{PS}$  is the phase space factor and  $|M_{Nuclear}|$  is the nuclear matrix element for the physics process describing the  $0\nu\beta\beta$  decay process[?].

Similar to beta decay, the  $2\nu\beta\beta$  process will cause a continuous spectrum in the detector while the  $0\nu\beta\beta$  process only has two electrons in the final state, which sum up to give a distinct energy peak. By measuring this exact energy, a detector with high energy resolution is able to search for the  $0\nu\beta\beta$  signal from the  $0\nu\beta\beta$  decay radioactive isotopes. Diverse technologies have been developed during the past decades. The following section lists some

of the mainstream experiments.

$$\Psi_R = \begin{bmatrix} \psi_R \\ \psi_R^C \end{bmatrix}, \Psi_L = \begin{bmatrix} \psi_L \\ \psi_L^C \end{bmatrix}, M = \begin{bmatrix} m_L^M & m^D \\ m^D & m_R^M \end{bmatrix}, \quad (2.11)$$

The mass eigenstates:

$$m_{\pm} = \frac{1}{2} [ (m_L^M + m_R^M) \pm \sqrt{(m_L^M - m_R^M)^2 + 4(m^D)^2} ],$$

from (2.3), there are 4 cases for discussion:

- (1) If  $m_L^M = m_R^M = 0$ ,  $m_{1,2} = m^D$ , neutrinos are pure Dirac particles.
- (2) If  $m^D \gg m_{L,R}^M$ ,  $\frac{m^D}{m_{L,R}^M} \rightarrow 0$ ,  $m_{1,2} = \frac{1}{2}m^D \left[ \frac{(m_L^M + m_R^M)}{m^D} + \sqrt{\left(\frac{m_L^M - m_R^M}{m^D}\right)^2 + 4} \right] \approx m^D$ , neutrinos are Pseudo-Dirac-Neutrinos.
- (3) If  $m^D = 0$ ,  $m_1 = m_L^M, m_2 = m_R^M$ , neutrinos are pure Majorana particles.
- (4) In the case of the seesaw mechanism, where  $m_R^M \gg m^D, m_L^M = 0$ , and for  $(\frac{m^D}{m_R^M})^2 \rightarrow 0$ , use  $(1+x)^\alpha \sim 1 + \alpha x$  (*if*  $x \rightarrow 0$ ), we get:

$$m_1 = m_- = \frac{\frac{1}{2}[(m_R^M)^2 - (m_R^M)^2 - 4(m^D)^2]}{m_R^M(1 + \sqrt{1 + 4(\frac{m^D}{m_R^M})^2})} \approx -\frac{(m^D)^2}{m_R^M},$$

$$m_2 = m_+ = \frac{1}{2}[m_R^M + m_R^M(1 + \frac{1}{2}(\frac{2m^D}{m_R^M})^2)] = m_R^M[1 + (\frac{m^D}{m_R^M})^2] \approx m_R^M.$$

For  $\mathcal{O}(1TeV)$ , the  $\nu$  mass is 0.1 eV

### 2.3.1 Status of Double Beta Decay Experiments

At the time of writing,

$0\nu\beta\beta$  in the range of  $10^{25} - 10^{26}$  year,

The GERmanium Detector Array (GERDA) experiment searches for  $0\nu\beta\beta$  of  $^{76}\text{Ge}$ . The experiment uses bare germanium crystals with an enrichment of up to  $\sim 87\%$   $^{76}\text{Ge}$  operated in a radiopure cryogenic liquid argon (LAr). GERDA Phase I had an exposure of 21.6 kg·yr and Phase-II started with 35.6kg from enriched material in December 2015. With combined data of Phase I and Phase II,

a total exposure of 82.4 kg·yr

GERDA reported in 2019 a lower limit half-life of  $T_{1/2}^{0\nu}(^{76}\text{Ge}) > 0.9 \times 10^{26}$  years at 90% C.L.[?, 5].

The Enriched Xenon Observatory (EXO) experiment uses 200-kg liquid Xenon (LXe) time projection chamber (TPC) to search for  $0\nu\beta\beta$  in  $^{136}\text{Xe}$ . In 2011 they observed the half life of double beta decay of  $^{136}\text{Xe}$  to be  $2.11 \times 10^{21}$  years and in 2014 they set a limit on  $T_{1/2}^{0\nu}(^{136}\text{Xe}) > 1.1 \times 10^{25}$  yr[?]. EXO is now upgrading to the next 5-tonne experiment (nEXO) and is expected to reach an exclusion sensitivity of  $T_{1/2}^{0\nu}(^{136}\text{Xe})$  to about  $10^{28}$  years at 90% C.L.[?].

Also looking into  $^{136}\text{Xe}$ , the KamLAND-Zen (ZERoneutrino) experiment exploits the existing facilities of KamLAND by setting a 3.08-m-diameter spherical inner balloon filled with 13 tons of Xe-loaded liquid scintillator at the center of the KamLAND detector.

liquid scintillator cocktail of 82% decane and 18% pseudocumene by volume, 2.7 g/L PPO.

photocathode coverage of 34%.

Their 2016 results from a 504 kg·yr exposure obtained a lower limit for the  $0\nu\beta\beta$  decay half-life of  $T_{1/2}^{0\nu}(^{136}\text{Xe}) > 1.07 \times 10^{26}$  yr at 90% C.L. and the corresponding upper limits on the effective Majorana neutrino mass are in the range 61 – 165 meV[?].

The Particle and Astrophysical Xenon Experiment III (PandaX-III) high pressure gas-phase time projection chamber (TPC)

The Cryogenic Underground Observatory for Rare Events (CUORE) experiment searches for  $0\nu\beta\beta$  in  $^{130}\text{Te}$ . CUORE is a ton-scale cryogenic bolometer array that arranges 988 tellurium dioxide ( $\text{TeO}_2$ ) crystals. CUORE reported first results in 2017 after a total  $\text{TeO}_2$  exposure of 86.3 kg·yr. An effective energy resolution of  $(7.7 \pm 0.5)$  keV FWHM and a background count of  $(0.014 \pm 0.002)$  counts/(keV·kg·yr) in the ROI were achieved in that data exposure. Combined with the early data (the data from the two precursor experiments, Cuoricino and CUORE-0), they placed a lower limit of  $T_{1/2}^{0\nu}(^{130}\text{Te}) > 1.5 \times 10^{25}$  yr at 90% C.L. and  $m_{\beta\beta} < (110 - 520)$  meV[6]. In five years live time, the experiment will give a projected sensitivity of  $9.5 \times 10^{25}$  yr at the 90% C.L. and set an upper limit on the effective

Majorana mass in the range  $50 - 130$  meV[38].

# Chapter 3

## The SNO+ Experiment

### 3.1 A Description of SNO+ Detector

#### 3.1.1 Overview

The SNO+ experiment is located at SNOLAB in Vale’s Creighton mine in Sudbury, Ontario, Canada. The deep underground facility of the SNOLAB provides a  $2092 \pm 6$  m flat overburden of rock, which is  $5890 \pm 94$  water equivalent meter (w.e.m). This rock overburden ensures an extremely low rate of cosmic muons passing through the detector. The rate is  $0.27 \mu/m^2/day$ , compared to an average flux of about  $1.44 \times 10^6 \mu/m^2/day$  at sea level[2].

The detector has been running since December 2016[?],

The SNO+ detector is the successor of the SNO experiment, which makes use of the SNO detector structure.

detector consists of an acrylic vessel (AV) sphere of 12 m in diameter and 5.5 cm in thickness. The AV sphere is concentric within a stainless steel photomultiplier(PMT) support structure (PSUP), which is a geodesic dome with an average radius of 8.4 m. The Hamamatsu 8-inch R1408 PMTs are mounted on the PSUP. 9394 PMTs are looking inward to the AV, giving a 50% effective coverage, while 90 PMTs are looking outward, serving as muon vetos. These two structures are housed in a rock cavity filled

with 7000 tonnes of ultrapure water (UPW) to provide both buoyancy for the vessel and radiation shielding.

main upgrades from SNO to SNO+ BiPo tagging on partial fill data

### 3.1.2 SNO+ Physics Phases

The SNO+ detector is designed for multi-purpose measurements of neutrino physics. The experiment will go through three phases[9]:

1. Water phase

The AV was filled with about 905 tonnes of ultra pure water (UPW). The detector has been collecting physics data since May 2017.

The main physics goal in this phase is to search for the invisible nucleon decay, which violates baryon number and is a prediction of Grand Unified Theory (GUT). In this decay mode,  $^{16}\text{O}$  decays into  $^{15}\text{O}^*$  or  $^{15}\text{O}^*$ , which de-excites and produces a  $\gamma$  ray of about 6 MeV.

During the water phase, different types of calibration runs have been taken. The detector responses, systematics and backgrounds are studied. Multiple physics analyses of solar neutrinos, reactor antineutrinos and nucleon decay are going on. The external backgrounds are also measured, which will be the same as the following two phases.

2. Scintillator phase

The AV will be filled with 780 tonnes of liquid scintillator, which is a mixture of linear alkylbenzene (LAB) as a solvent and 2 g/L of 2,5-diphenyloxazole (PPO) as a fluor.

In this phase, the main physics goal is to measure low energy solar neutrinos: the CNO, pep and low energy  $^8\text{B}$  neutrinos. The pep neutrinos are mono-energetic, with  $E_\nu=1.442$  MeV and their flux is well predicted by the Standard Solar Model. A measurement of the pep neutrinos will give more information of the matter effects in neutrino oscillations[?].

The solar metallicity is the abundance of elements heavier than  $^4\text{He}$  (called “metal” elements in the context of astronomy). It is poorly constrained and the predictions from different solar models disagree with each other. A measurement of the CNO neutrinos can give the abundance of  $^{12}\text{C}$ ,  $^{13}\text{N}$  and  $^{15}\text{O}$  and can thus resolve the metallicity problem[?].

Geoneutrino, reactor antineutrino and supernova neutrino detections are additional goals.

A six-month period of scintillator filling and six to twelve months of data-taking are expected for this phase. During the filling, it is planned to operate the partially filled detector at a water level about 4.4 m for about two weeks. This partial filled transition phase is mainly aimed to understand the in-situ backgrounds of scintillator.

### 3. Tellurium loading phase

In this final phase, 0.5% natural Tellurium by mass will be loaded into the scintillator. Higher loading concentrations would be possible for a further loading plan[37]. The  $^{130}\text{Te}$  is a double beta decay isotope. The main purpose in this phase is searching for  $0\nu\beta\beta$  in  $^{130}\text{Te}$ .

#### 3.1.3 Detection Principle

##### Optical Cherenkov Radiation

For any charged particle travelling in a transparent medium at an ultrarelativistic speed (a speed greater than the local phase speed of light in the medium), an electromagnetic radiation, called Cherenkov radiation, can be emitted from the coherent response of the medium under the action of the field of the moving particle[26, 31].

Suppose a charged particle moves in a transparent, isotropic and non-magnetic medium and creates an electromagnetic wave. The electromagnetic wave propagates with a wave number  $k = n \cdot \omega/c$ , where  $c$  is the speed of light in vacuum,  $n$  is the real-valued refractive index and  $\omega$  is the frequency. If the particle travels uniformly along x axis with a velocity of  $v$ , the x-component of the wave vector is  $k_x = \omega/v$ . For a freely propagating wave,  $k > k_x$ , therefore  $v > v_p = c/n(\omega)$ , where  $v_p$  is the phase velocity in the medium. Under this condition that the speed of the charged particle is greater than the  $v_p$ , the Cherenkov radiation is emitted with a frequency of  $\omega$ [31].

The Cherenkov angle,  $\theta_c$  is the angle between the direction of the particle and the direction of Cherenkov emission and it is well-defined by  $\cos \theta_c(\omega) = \frac{c}{n(\omega)v}$ . The radiation

is distributed over a surface of a cone with the half-opening angle  $\theta_c$ .

Consider the condition  $v > v_p = c/n(\omega)$ , for the case of  $e^-$  travelling in a water detector, if neglecting the dependency on  $\omega$ ,  $n_{water} \simeq 1.33$  [44], then  $\theta_c \simeq 41.25^\circ$  and  $v_p \simeq 2.254 \times 10^8 \text{ m/s}$ , which corresponds to a kinetic energy  $E_k = (\gamma - 1)mc^2 = 0.264 \text{ MeV}$  for  $e^-$ , where  $\gamma = 1/\sqrt{1 - v_p^2/c^2}$ . This is the lowest kinetic energy to create Cherenkov radiation, which is referred to the Cherenkov threshold ( $E_{thresh}$ ). In the case that the LAB-PPO liquid scintillator is the medium,  $n \simeq 1.50$ [46],  $\theta_c \simeq 48.19^\circ$  and for  $e^-$ ,  $E_{thresh} \simeq 0.175 \text{ MeV}$ .

For a particle with a charge of  $ze$ , the number of photons produced by Cherenkov radiation per unit path length and per unit frequency of the photons is given by[34]:

$$\frac{d^2N}{d\omega dx} = \frac{\alpha^2(ze)^2}{c} \sin^2 \theta_c = \frac{z^2\alpha}{c} \left(1 - \frac{1}{\beta^2 n^2(\omega)}\right),$$

where  $\alpha$  is the fine structure constant.

Translate the frequency into the wavelength ( $\lambda = 2\pi\omega$ ) and integrate over the wavelength, we have the number of photons and  $x$  is along the particle track[34]:

$$\frac{dN}{dx} = 2\pi(ze)^2 \alpha \sin \theta_c \int_{\lambda_1}^{\lambda_2} \frac{d\lambda}{\lambda^2},$$

For optical photons with wavelengths ranging from 350 to 550 nm (typical PMT detection sensitive range), the above formula can be calculate into[34]:

$$\frac{dN}{dx} = 476(ze)^2 \sin^2 \theta_c \text{ photons/cm.}$$

For the Cherenkov radiation caused by  $e^-$  in a water detector,  $dN/dx \simeq 207 \text{ photons/cm}$ ; while in the LAB-PPO case:  $dN/dx \simeq 264 \text{ photons/cm}$ . In a realistic measurement, the detection efficiency and the coverage of photon sensors are also required to be taken into account.

## Scintillation Detection

In the liquid scintillator case, besides the Cherenkov radiations caused by an event, the majority of lights come from scintillation.

prompt emission of scintillation light, which is called fluorescence delayed emission of scintillation light, which is called delayed fluorescence or phosphorescence.

### 3.1.4 Electronics

The SNO+ electronics system includes trigger and readout systems, which record the time and charge information of PMT signals. The system can measure signals with a nanosecond-level timing resolution and single-photon level charge resolution and handle a rate of several kHz for normal operations.

Linear Alkyl Benzene (LAB)

is provided by CEPSA Química Bécancour Inc. Organic liquid scintillators The advantages of LAB are:

- It has very low levels of natural radioactive contaminants such as U, Th and K.
- High light yield and attenuation length.
- It has fast timing response different timing spectrum for  $\alpha$  and  $\beta$  events, which enables an  $\alpha - \beta$  discrimination.
- High flash point and low toxicity for lab safety.
- appropriate density for mechanical stability
- Good stability and chemically compatible with detector materials, mainly the AV.
- Low cost.

Te-loaded liquid scintillator (TeLS)

To load the tellurium into the liquid scintillator, a compound is made by condensation reactions between telluric acid (TeA) and 1,2-butanediol (BD), with N,N-dimethyldodecylamine (DDA) being used as a stabilization agent.

### 3.2 Monte Carlo Simulation for SNO+

The SNO+ collaboration has developed a software framework, called the Reactor Analysis Tool (RAT), which integrates a Monte Carlo simulation of the SNO+ detector and event-based analysis tools (for online and offline event analysis) since the beginning of the program. This software was originally developed by Stan Seibert for Braidwood Collaboration for a generic KamLAND like detector. It is also used by the other astroparticle physics experiments, such as DEAP/CLEAN, CLEAR and potentially for Darkside-50.

Geant4 Toolkit and incorporates ROOT libraries for data handling and analysis.

The RAT Monte Carlo was originally developed for the Braidwood Collaboration utilising software developed for a generic KamLAND like detector, called Generic Liquid Scintillator GEANT4 simulation (GLG4). It was branched and developed into the specialist SNO+ version, starting in 2006/2007.

GLG4sim

Braidwood

combines both Monte Carlo simulation of the Braidwood detector with event-based analysis tasks, like reconstruction. The primary goals are:

Make it easy to analyze Monte Carlo-generated events as well as data from disk using the same software with only a few command changes. Even in the proposal R&D phase, where there is no real data, this is still useful for dumping Monte Carlo events to disk to be analyzed by another job. When there is real data, being able to do the analysis with the same code path as was used on Monte Carlo is very reassuring. Allow for a modular, user-

controlled analysis of events. This includes allowing the user to selected which analysis tasks to perform (different fitters, pruning unneeded data from the event data structure, etc.). It should also be relatively straightforward for users to introduce their own code into the analysis process. Separate analysis into small tasks which can be developed asynchronously by different people, yet integrated with minimal (or perhaps zero) pain. Integrate into existing GEANT4 and GLG4sim efforts with a minimum of code duplication. As much as possible, RAT should be designed incorporate upgrades of these packages just by relinking. No cut and paste of code (mainly a question with GLG4sim). Design the detailed processes of data acquisition and trigger systems are [9].  
[3]

## Event Reconstruction

### 4.1 Reconstruction of the SNO+

event vertex

### 4.2 Reconstruction Algorithms for Position, Time and Energy of Events in SNO+

### 4.3 Multi-path Vertex Reconstruction Algorithm for SNO+

A Multi-path (MP) reconstruction framework was developed by the University of Alberta group as an additional vertex reconstruction algorithm for SNO+. This framework was first developed by Aksel Hallin to reconstruct and investigate the event vertex for the data taken from an early stage of SNO+ when the detector was partially filled with water at the end of 2014[23]. It was further developed by David Auty and Kalpana Singh for investigating the wavelength shifter and water events[10, 40, 41, 1]. Jeff Tseng restructured the related codes into more flexible and efficient C++ codes and implemented into the RAT software[25].

In this framework, the fitter is adapted for various SNO+ physics phases, including the water phase, a conceptual wavelength shifter (WLS) phase, the partial-fill phase and the scintillator phase (with and without Tellurium loaded). In the SNO+ water phase, the

cavity and the AV are both filled with ultra-pure water. This is a relatively simple geometry since everything inside the PSUP can be simplified as water. Therefore, we start with the MP water fitter (the MPW fitter) to explain the reconstruction concepts.

The MPW fitter fits for position, time and direction of an event in SNO+ water phase. First, the fitter throws a random position built up by random variables which are uniformly distributed inside a sphere with a radius of 10 *meters* (larger than the actual PSUP radius  $r_{PSUP} = 8.39\text{ m}$ ). Meanwhile, a random event time is also generated, following a uniform distribution in a range of 100 to 300 *ns*. The Class Library for High Energy Physics (CLHEP) is used for creating pseudo-random numbers (see the Appendix A.1 for details). With random event position and time, a random vertex works as a trial event vertex.

Connecting the trial event vertex to the triggered PMTs, the fitter evaluates a timing parameter, called the time residual ( $t_{res}$ ), by calculating the time of flight for photons travelling along the paths between the event position to the triggered PMT positions (light paths).

The time residual is defined as:

$$t_{res} = t_{PMT} - t_{transit} - t_{event},$$

where  $t_{PMT}$  is the PMT triggered time recorded by the detector,  $t_{event}$  is the time when an event occurs, and  $t_{transit}$  is the total transit time (or time of flight) taken by a photon travelling from the event position ( $\vec{x}_{event}$ ) to the triggered PMT ( $\vec{x}_{PMT}$ ) and crossing different materials in the detector.

To calculate the  $t_{transit}$ , the fitter uses photons from prompt time window (prompt light) and assumes that photons propagate in straight lines (straight light paths). Here it is simple:  $t_{transit} = |\vec{x}_{event} - \vec{x}_{PMT}|/v_{water}$ . Detailed calculations, such as the refraction and reflection when the lights cross different detector materials, absorptions and scatterings from the materials, as well as the lensing effects caused by the spherical structure of the acrylic vessel, are neglected. We found that without these details, the fitter can still produce results consistent with the ones using detailed calculations. For a trial vertex ( $\vec{x}_0, t_0$ ), the fitter calculates a set of  $t_{res}$  values with respect to all the triggered PMTs. These values

are fed into a likelihood function:

$$\ln \mathcal{L}(\vec{x}_0, t_0) = \sum_{i=1}^{\text{Nhits}} \ln P(t_{res}^i),$$

where  $t_{res}^i$  is the time residual calculated from the  $i^{th}$  triggered PMT and Nhits here stands for the number of total triggered PMTs by an event.

A pre-set 1-dimensional (1D) probability density function (PDF) is used for fitting the model. The pdf was taken from the bench-top timing profile measurement as well as the measured detector response.

$P(t_{res}^i)$  is the probability returned from the PDF for the  $i^{th}$  triggered PMT and a trial event vertex.

The Levenberg-Marquardt method, which is commonly used for fitting the nonlinear model for multiple parameters, is used as an optimizer to find the best fit event parameters (position, time and direction). Appendix A.2 describes this method; A.3 describes the implementation of the method to the MultiPath fitter framework. Also see [22, 39].

As we will see in the following sections, one of the biggest jobs for the fitter is to calculate the  $t_{transit}$  by evaluating light paths. In the water phase, we consider photons created in an event travelling along straight line paths and the paths are always in water. In the other situations, for example, when the acrylic vessel is filled with the wavelength shifter or scintillator, the light path calculations will be modified.

Figure. 4.1 shows the reconstruction concepts for position and direction.

**Fitter Structure** The MPW fitter consists of: Fitter Data : Includes physics constants, set-values and pdfs for the MPW fitter. These parameters are set in the MPW database.

- Water reflection index (water\_RI, or  $n_{water}$ ), used for group velocity ( $v_g = c/n_{water}$ ) calculation.

The MPW fitter currently uses one fixed number for  $n_{water}$ , rather than a function of wavelengths. The value of  $n_{water}$  can be tuned to give the lowest biases of the fitted positions to the Monte Carlo and to give the lowest RMS of fitted results as well. But the effect of  $n_{water}$  can also be corrected by the drive correction afterwards. Currently  $n_{water} = 1.38486$  is

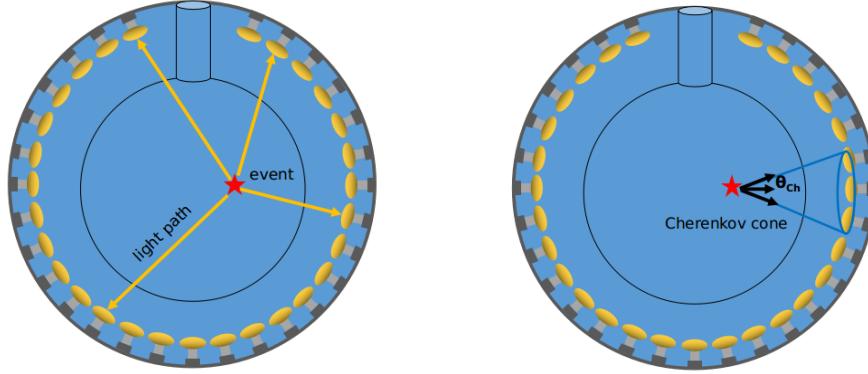

Figure 4.1: Diagrams of position (left) and direction (right) reconstruction in SNO+ water phase.

obtained by analyzing the time of flight from the  $^{16}\text{N}$  central run-100934 data reconstructed by the MPW fitter.

- Constants for fit setting: Includes the fitter tolerance, the maximum iterations for the Multi-path Fitter to converge, time offset, radius cut for position vertex, fitting bin-width and steps.

- Other physics constants: air reflection index (air\_RI), psup radius.

- PMT response time (timing) pdf for the position reconstruction, as shown in 4.2. The pdf shown in red line is modified from the measured PMT response time distribution from SNO time and the late light response is forced to be de-weighted (black). The pdf is modified in [-100,-4] ns region to match the time residual spectrum obtained from

Figure 4.2: PMT response time as the timing pdf.

- PMT angular response pdf for the direction reconstruction, as shown in 4.3. It is taken from the Monte Carlo simulation of 5 MeV electrons traverse in the AV with one direction.

Figure 4.3: PMT angular distribution as the angular response pdf.

- Likelihood Calculation Classes: Constructs likelihood functions, calculates likelihoods and their derivatives. For the MPW fitter, there are two classes: WaterPosition for position reconstruction and WaterDirection for direction reconstruction. The WaterPosition class

tackles with 4 parameters ( $x, y, z, t$ ) and the WaterDirection class tackles with 2 parameters ( $\theta, \phi$ ).

- Multi-path Fitter: Processes the MPW fitter and finds the best-fit of the likelihood function. It is a general processor and is shared with the fitters using the Multi-path Fitter, including the MPW fitter, air-water (AW) fitter, wavelength-shifter (WLS) fitter and scint-water fitter (being developed). It processes a certain fitter by being assigned the fitter name in macro. It processes the fitter event by event: for every triggered event, it first calls PMT selectors (ModeCut or StraightTimeResidualCut) and sends the information of the reduced PMTs to a certain Likelihood Calculation Class for likelihood calculations. The Likelihood Calculation Class sends back the values of likelihoods and their derivatives, so the Multi-path Fitter does not care about how the likelihood functions are constructed and how the likelihoods and derivatives are calculated. Using these values, it constructs an  $n \times n$  Hessian matrix ( $n$  is the number of fitting parameters defined in Likelihood Calculation Class) and uses the Levenberg-Marquardt (MRQ) method to maximize the likelihood and finds the best-fit values. For the MPW, if the likelihood maxima is found 5 times for any position and direction then values are returned as the fitted position and direction. For the MPW case, it calls the ModeCut and fits for the position and time; then it calls the StraightTimeResidualCut and fits for the directions.

- Dump Likelihood: It is a function inside the Multi-path Fitter. It stores the likelihood surfaces and their derivatives from the fitting of the Multi-path Fitter to check whether the fitter finds global or local maximum of the interested events and to check the reconstruction performances. It requires a switch on/off parameter and the GTIDs of the interested events (a list of GTIDs) from the MPW database.

- SDecompQRH: It is a fit method class modified from ROOT TDecompQRH. It is used by the Multi-path Fitter to invert the Hessian matrix. Compared to ROOT, Solve() for  $Ax=b$  is modified to zero the component of  $x$  for which the diagonal element in  $R$  is small. This allows a Levenberg-Marquardt optimization to continue in many cases when the matrix is singular. For the MPW case, it is used to invert  $4 \times 4$  matrix of the WaterPosition

Class while the inversion of  $2 \times 2$  matrix of the WaterDirection is calculated directly.

- ModeCut: The same class used by Rat. Selects the PMTs of an event by a mode time window. For the MPW, the optimized window is  $[-50 + t_{mode}, 100 + t_{mode}]$  ns obtained from

- StraightTimeResidualCut: Selects the PMTs of an event by a time residue window. This selector requires a fitted position and fitted time. It calculates the time residue directly by assuming straight light path, which is the same method used by Multi-path fitter. For the MPW case, it is used for the direction fit after the position and time are reconstructed. The default window is  $[-10, 250]$  ns.

## 4.4 MPW Position and Direction Reconstructions

### 4.4.1 Vertex Reconstruction

For the position reconstruction of the MPW fitter, the likelihood function simply calculates the likelihood assuming straight line paths of prompt light from a position vertex  $\vec{X}_0$  (fVertex) and a starting time offset  $t_0$  to each of the hit PMTs.

We define the position difference  $\vec{X}_{\text{diffCh}} = \vec{X}_0 - \vec{X}_{\text{pmt}}$ , then the time of flight for prompt light is  $t_{\text{Ch}} = |\vec{X}_{\text{diffCh}}|/v_g$  and  $L_{\text{Ch}} = L(t_{\text{Ch}})$ .

The derivatives of the likelihood function can be calculated from explicit mathematical forms as:

$$\frac{\partial L}{\partial t_0} = \frac{dL_{\text{Ch}}}{dt_{\text{Ch}}},$$

$$\frac{\partial L}{\partial x} = \frac{\partial L_{\text{Ch}}}{\partial t_{\text{Ch}}} \frac{dt_{\text{Ch}}}{dx} = -\frac{dL_{\text{Ch}}}{dt_{\text{Ch}}} \frac{X_{\text{diffCh}}}{|\vec{X}_{\text{diffCh}}| \cdot v_g},$$

$$\frac{\partial L}{\partial y} = -\frac{dL_{\text{Ch}}}{dt_{\text{Ch}}} \frac{Y_{\text{diffCh}}}{|\vec{X}_{\text{diffCh}}| \cdot v_g},$$

$$\frac{\partial L}{\partial z} = -\frac{dL_{\text{Ch}}}{dt_{\text{Ch}}} \frac{Z_{\text{diffCh}}}{|\vec{X}_{\text{diffCh}}| \cdot v_g},$$

where  $\frac{dL_{\text{Ch}}}{dt_{\text{Ch}}}$  can be calculated numerically from the timing pdf.

In the WaterPosition class, it starts with a random  $(\vec{x}_0, t_0)$  as seed and calculates the likelihoods and their derivatives for various paths. These values are sent to the Multi-path Fitter, which is fitting 4 parameters:  $x, y, z, t$  and to maximize the likelihood function through the MRQ method and to find the best-fit positions.

#### 4.4.2 Direction Reconstruction

$\vec{u}_0 = (\cos \phi \sin \theta, \sin \phi \sin \theta, \cos \theta)$  (fDirection), where the  $\theta$  is zenith angle and  $\phi$  the azimuth.  $\cos \theta_{\text{Ch}}$  is the angle between  $\vec{u}_0$  and  $\vec{X}_{\text{diffCh}}$ , which is taken as the fitting parameter of the likelihood function for the direction reconstruction. For the i-th hit PMT,  $\cos \theta_{\text{Ch}}^i = \vec{u}_0 \cdot \frac{\vec{X}_{\text{diffCh}}^i}{|\vec{X}_{\text{diffCh}}^i|}$ , then the likelihood function is:

$$L(\vec{u}_0) = \sum_{i=1}^{\text{Nhits}} L_i(\cos \theta_{\text{Ch}}^i),$$

The derivatives have explicit mathematical forms:

$$\frac{\partial L}{\partial \theta} = \frac{dL_{\text{Ch}}}{d \cos \theta_{\text{Ch}}} \frac{d \cos \theta_{\text{Ch}}}{d \theta} = \frac{dL_{\text{Ch}}}{d \cos \theta_{\text{Ch}}} \frac{d \vec{u}_0}{d \theta} \cdot \frac{\vec{X}_{\text{diffCh}}}{|\vec{X}_{\text{diffCh}}|},$$

where  $d \vec{u}_0 / d \theta = (\cos \phi \cos \theta, \sin \phi \cos \theta, -\sin \theta)$  and

$$\frac{\partial L}{\partial \phi} = \frac{dL_{\text{Ch}}}{d \cos \theta_{\text{Ch}}} \frac{d \cos \theta_{\text{Ch}}}{d \phi} = \frac{dL_{\text{Ch}}}{d \cos \theta_{\text{Ch}}} \frac{d \vec{u}_0}{d \phi} \cdot \frac{\vec{X}_{\text{diffCh}}}{|\vec{X}_{\text{diffCh}}|},$$

where  $d \vec{u}_0 / d \phi = (-\sin \phi \sin \theta, \cos \phi \sin \theta, 0)$ .  $\frac{dL_{\text{Ch}}}{d \cos \theta_{\text{Ch}}}$  can be calculated numerically from the PMT angular response pdf.

In the FitterWaterDirection class, it starts with a random  $(\theta_0, \phi_0)$  as seed and calculates the likelihoods and their derivatives for various paths. These values are sent to the Multi-path Fitter, which is now fitting 2 parameters:  $(\theta, \phi)$  and to maximize the likelihood function through the MRQ method and to find the best-fit directions.

#### 4.4.3 Drive Correction

An effect of ‘fitter pull’ in the event vertex reconstruction utilizing the Cherenkov light was observed in the SNO experiment. The cause of this effect is that the Cherenkov photons

trigger the majority of PMT hits with early timing and these hits are located within the Cherenkov cone; while the scattered or reflected light with later timing trigger PMT hits throughout the detector. This

as illustrated in Fig. . .

modified from Fig. C.2 in [14].

shift

fitter pull.

[14, 16].

Once the MPW fitter obtains the fitted position and direction, a drive correction is applied on the fitted position by  $\vec{X}_{\text{corrected}} = p_0 \vec{X}_{\text{fit}} + p_1 \vec{u}_{\text{fit}}$ , where  $p_0$  and  $p_1$  are the correction parameters.

To obtain the values of  $p_0$  and  $p_1$ , we generated electron events distributed isotropically inside the AV. The simulations of 2, 3, 4, ..., 10 MeV electrons are produced. Then the MPW fitter is applied on each simulations and returns the results of  $\vec{X}_{\text{fit}}$  and  $\vec{u}_{\text{fit}}$ . Take the Monte Carlo generated positions  $\vec{X}_{MC}$  as the true positions, for all the fitted events, a  $\chi^2$  function is calculated by:

$$\chi^2 = \sum_{i=1}^{N_{\text{events}}} [\vec{X}_{MC}^i - (p_0 \vec{X}_{\text{fit}}^i + p_1 \vec{u}_{\text{fit}}^i)]^2$$

The  $p_0$  and  $p_1$  are obtained by minimizing the  $\chi^2$  function. When doing the  $\chi^2$  calculation, the fitted events of  $|\vec{X}_{\text{fit}} - \vec{X}_{MC}| > 3 \text{ m}$  are thrown away to improve the  $\chi^2$  minimization results.

For the 2 to 10 MeV electrons simulations, the obtained values of  $p_0$  and  $p_1$  are energy or Nhit dependent. However, it does not improve the results if using the Nhit dependent functions  $p_0(Nhit)$  and  $p_1(Nhit)$  as drive corrections. Finally we take the average values from the 5 to 10 MeV electrons simulations and the drive correction is set as  $\vec{X}_{\text{corrected}} = 0.995765 \vec{X}_{\text{fit}} + -63.826 \vec{u}_{\text{fit}}$ .

It is important to note that since the drive correction parameters are obtained from the reconstructions of Monte Carlo, it depends on the Monte Carlo and the results of

reconstruction. Therefore, the  $n_{water}$ , mode cut and time residue cut affecting the fitted results will also affect the drive correction parameters, but not significantly.

By fitting the simulations of 5 MeV electrons generated at the detector center and travelling along +X direction, the drive effect of the MPW fitter causes a  $\sim 50$  mm biases from the detector center along +X axis. The drive correction reduces this drive bias down to  $\sim 0.2$  mm. For the reconstruction of  $^{16}\text{N}$  data, the drive correction can reduce the fitted position RMS by  $\sim 20$  mm.

## 4.5 Vertex and Direction Reconstruction for Wavelength-shifter

## 4.6 Vertex Reconstruction for Partial-fill and Scintillator Phases

In the partial fill geometry, photons will travel with different speeds as they pass through two different mediums, water and scintillator. Assuming a straight light path, the MP Partial Fitter mainly calculates the total length of the light path ( $|\vec{l}_p| = |\vec{X}_{\text{PMT}} - \vec{X}_0|$ ) and separates it into the lengths in scintillator ( $d_{sp}$ ) and in water ( $|\vec{l}_p| - d_{sp}$ ).

As illustrated in Figure 4.4, a detailed calculation of  $d_{sp}$  includes evaluations of (1) light path and neck (line-cylinder) intersection; (2) light path and AV sphere (line-sphere) intersection and (3) light path and water-scintillator interface (line-plane) intersection.  $d_{sp}$  is further separated into the path length in neck ( $d_{sp,neck}$ ) and in AV ( $d_{sp,AV}$ ).

Then the time of flight is obtained by:

$$tof = \frac{|\vec{l}_p| - d_{sp}}{v_{gr,water}} + \frac{d_{sp}}{v_{gr,scint}}, \quad (4.1)$$

The time residual is  $t_{res} = t_{\text{PMT}} - tof - t_0$ .

If  $d_{sp} = 0$ , the light path is always in the water. In this case, the fitter is the same as the MP Water Fitter. The fitter fits with the MP Water Fitter pdf. Once the light path passes through the scintillator region, the fitter fits with a scintillator timing pdf, the PMT time response modified to photon propagation time in scintillator, as shown in Figure 4.5.

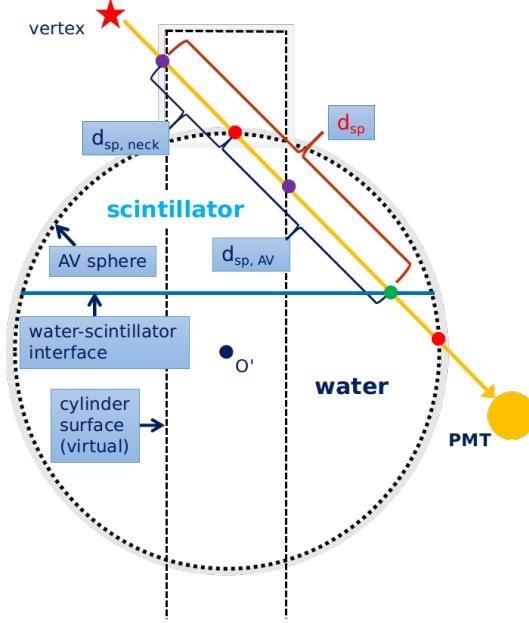

Figure 4.4: Light path calculation for the MP Partial Fitter.

The performance of the fitter was studied with MC simulations. In a partial fill geometry with water level at 4.4 m, 2.5 MeV electrons are simulated inside the AV in the scintillator region only, the water region only and the whole AV region.

Figure 4.6 and Figure 4.7 show the MP Partial Fitter reconstructed results for these simulations. Figure 4.6 shows the biases between the fit positions and MC positions, projected on the x axis. The distributions of position biases are fit with Gaussian functions. The values of Gaussian mean and sigma quantify the fit biases and resolutions. Table 4.1 lists these values.

Table 4.1: Reconstructed position biases and resolutions for simulated events in partial fill.

regions of simulated events	bias (mm)	resolution (mm)
scintillator region	-1.0	73.9
water region	-10.7	385.1
full region	6.9	331.72

For the events in water, the fit bias and resolution is comparable to the water phase results in Table 4.3. The events in the scintillator region have smaller fit bias and better resolution due to more triggered PMTs in the reconstruction.

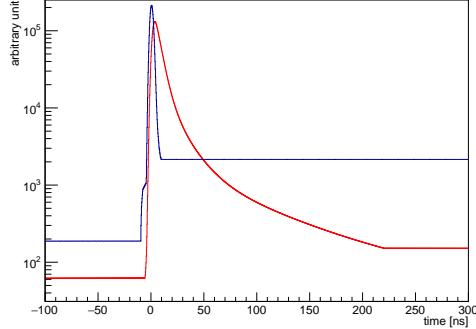

Figure 4.5: The timing pdfs used by the MP Partial Fitter. Blue: the timing pdf used by the MP Water Fitter; Red: the scintillator timing pdf.

Figure 4.7 shows the fit  $\sqrt{x^2 + y^2}$  vs. fit  $z$  positions. It shows that the fitter can distinguish different events in the water or scintillator region. The fitter gives reasonable results of the three different MC simulations.

For the partial-phase geometry, the SNO+ acrylic vessel can be considered as composed of the neck (cylinder), AV sphere and water-scintillator interface (plane). The ray coming from the vertex to the PMT can intersect with these three geometries.

line-sphere intersection and line-plane intersection

$a_1, a_2$  and  $a_3$

trial position  $\vec{X}_0 = (x_0, y_0, z_0)$ , PMT position  $\vec{X}_{\text{pmt}} = (x_{\text{pmt}}, y_{\text{pmt}}, z_{\text{pmt}})$

ray-vector  $\vec{l}_0 = \vec{X}_0 + a \cdot \vec{u}$ , where  $a$  is the distance between vertex and intersection point. It is the parameter to be determined.  $\vec{u} = (\vec{X}_{\text{pmt}} - \vec{X}_0)$  is the direction of the ray-vector/light path.

$\vec{O}_{av}$  is the origin of the AV sphere. In the PSUP coordinate,  $\vec{O}_{av} = (0, 0, 108)$  mm. For the ray-sphere intersection,  $(\vec{l}_0 - \vec{O}_{av})^2 = r_{av}^2$

To solve this equation, let  $\Delta = [(\vec{X}_0 - \vec{O}_{av}) \cdot \vec{u}]^2 - (\vec{X}_0 - \vec{O}_{av})^2 + r_{av}^2$  then

$$a_{+,-} = -(\vec{X}_0 - \vec{O}_{av}) \cdot \vec{u} \pm \sqrt{\Delta}, \text{ if } \Delta > 0$$

if  $\Delta \leq 0$ , there is no intersection point or only one intersection point at the AV, the ray never passes through the AV sphere.

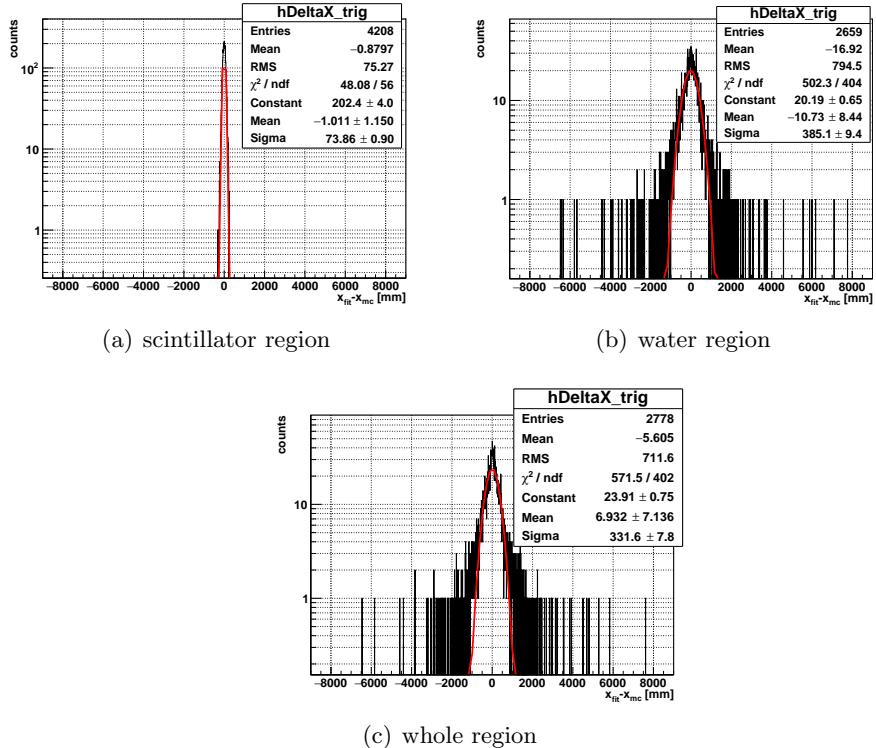

Figure 4.6: Distributions of fit position bias projected on x axis ( $x_{fit} - x_{MC}$ ).

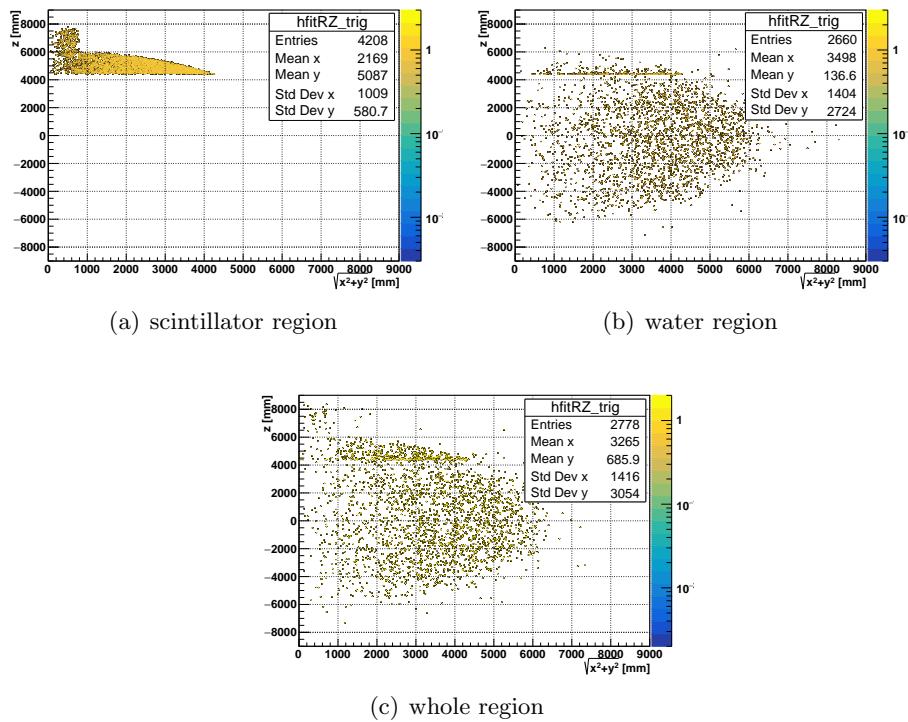

Figure 4.7: Fit results:  $\rho_{fit} = \sqrt{x_{fit}^2 + y_{fit}^2}$  vs.  $z_{fit}$ .

For the ray-plane intersection,  $l_{0,z} = Z_{split}$ , where  $Z_{split}$  is the water level. If  $u_z = z_{pmt} - z_0 = 0$ , the ray is parallel to the plane and never intersects the plane. To solve this equation, we have  $a = (Z_{split} - z_0)/u_z = (Z_{split} - z_0)$ , if  $u_z \neq 0$ . Let:

$$a_3 \equiv a = \frac{(Z_{split} - z_0)|\vec{X}_{pmt} - \vec{X}_0|}{z_{pmt} - z_0} \quad (\text{if } z_{pmt} - z_0 \neq 0),$$

For the ray-cylinder intersection,  $l_{0,x}^2 + l_{0,y}^2 = r_{neck}^2$ , where  $r_{neck}$  is the radius of the neck cylinder.

$$\text{time of flight (tof)} = (a_+ - a_3)/v_{gr,scint} + [|\vec{X}_{pmt} - \vec{X}_0| - (a_+ - a_3)]/v_{gr,water}$$

$$\frac{\partial L}{\partial splitZ} = \frac{\partial L}{\partial tof} \cdot \frac{\partial tof}{\partial splitZ} = \frac{\partial L}{\partial tof} \cdot \frac{\partial a_3}{\partial splitZ}$$

$$\frac{\partial L}{\partial splitZ} = 0$$

Radial bias is defined as the difference between the fitted and true position, projected along the radial component (unit vector) of the true position [16].

$$(\vec{X}_{fit} - \vec{X}_{true}) \cdot \hat{X}_{true}$$

The value of the mean radial bias is taken by fitting the histogram of the distributions of radial biases with a Gaussian profile and then get the mean of the fitted Gaussian profile.

## 4.7 PMT Selectors for the Fitter

Several PMT selectors are used to select or remove PMTs from all the recorded PMTs triggered by an event and send the selected PMTs to the fitter for reconstruction. They are developed for optimizing the fitter or boosting up the fit speed:

- Straight Light Path Time Residual Cut Selector

This selector is used for the direction reconstruction for the SNO+ water phase. In the

selector, the value of time residual ( $t_{res}$ ) is calculated for each triggered PMTs from an event and the PMT with a  $t_{res}$  value in a prompt time window of  $[-10.0, 120.0] \text{ ns}$  is selected for the fitter. The selector calculates  $t_{res}$  by using straight line light path, which is the same to the MultiPath water fitter. This can remove the PMTs triggered by photons with late timing, such as the photons reflected off the detector elements (late light) and keep the possible Cherenkov ring hit pattern clear for the direction fitter to fit. Also, dropping the irrelevant PMTs can potentially boost up the fit speed.

- Mode Cut Selector

This selector checks the hit time ( $t_{PMT}$ ) distributions of all the triggered PMTs and finds a mode value of the hit time ( $t_{mode}$ ). If  $t_{mode}$  fails to be found, it calculates a median value ( $t_{median}$ ) instead. Then it selects the PMT with  $t_{PMT} \in [t_{mode} - 50, t_{mode} + 100] \text{ ns}$ . This selector is used to remove the PMTs triggered by noise and light light from reflection[33].

- Uniform PMT Selector

This selector is mainly designed for the partial-fill phase and the scintillator phase when an event can trigger a large amount of PMTs. It reduces the number of the triggered PMTs to a designated number ( $n_{select}$ ) in order to boost up the fit speed. When an event triggers  $N$  calibrated PMTs, the selector goes through these recorded PMTs and uniformly picks up one PMT by an interval of  $\lceil N/n_{select} \rceil$ . If  $N \leq n_{select}$ , the selector does nothing. By doing this, the selector uniformly reduces the number of the PMTs for the fitter without an obvious bias.

- Earliest Hit PMT Selector

Similar to the uniform PMT selector, this selector reduces the number of the triggered PMTs to boost up the fit speed. It first groups the PMTs by their positions in the PMT support sphere. Take the centre of the sphere as coordinate origin, the sphere is divided by the azimuth angle  $\phi$  (as longitude) and zenith angle  $\theta$  (as latitude). In the sphere, the positions of the PMTs in  $\phi$ , ranging in  $[-\pi, \pi]$ , is uniformly divided

into  $n$  intervals while the positions of the PMTs in  $\cos \theta$ , ranging in  $[-1, 1]$ , is also divided into  $n$  intervals. Thus, the PMTs are grouped into  $n \times n$  panels, see Fig. 4.8.

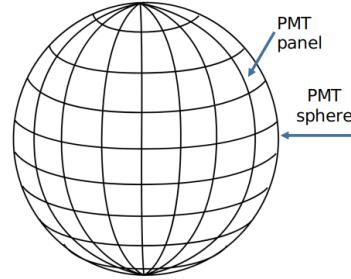

Figure 4.8: Group the PMTs by dividing the PMT sphere with latitudes and longitudes.

For each panel, the selector first drops the PMTs triggered too early ( $t_{\text{PMT}} < 100 \text{ ns}$ , where  $100 \text{ ns}$  is set as a default threshold). These PMTs could be triggered by noises, such as pre-pulsing. In the rest of the PMTs, the selector picks up one PMT with the earliest  $t_{\text{PMT}}$  in each panel. Thus the number of the PMTs is reduced to  $n \times n$  for the fitter, i.e.,  $n_{\text{select}} = n \times n$ . If  $N \leq n_{\text{select}}$ , the selector does nothing.

We can also use the other timing parameter, such as the  $t_{\text{mode}}$  or the  $t_{\text{median}}$  for selecting the PMT in each panel. However, tests from the simulations for the scintillator phase show that using the earliest hit time gives less fit biases and better fit resolutions.

## 4.8 $^{16}\text{N}$ Calibration Test

During the water phase, an Nitrogen-16 ( $^{16}\text{N}$ ) calibration source was deployed for internal detector calibration scans in June and November, 2017 and external detector scans in March, 2018.

The  $^{16}\text{N}$  calibration runs provide an ideal test of fitter performance. From a comparison of reconstructions for data and MC, we can also extract the resolution and bias of the fitter. The  $\gamma$  rays emitted from the  $^{16}\text{N}$  source interact with the water in the detector mainly

via Compton scattering. Figure ?? shows the spatial distributions of the first  $\gamma$ -ray interaction positions projected on the x axis (called spatial distribution  $S(x)$ ) obtained from MC simulation. The  $^{16}\text{N}$  source is considered as an electron source with a known spatial distribution[?]. For simplicity, in the following we always discuss the  $x$  component of the position vector  $\vec{X}$ .

A position resolution function is defined for the reconstructed electron position distribution[?]:

$$R(x) = \frac{1 - \alpha_e}{\sqrt{2\pi}\sigma_p} \exp\left[-\frac{1}{2}\left(\frac{x - \mu_p}{\sigma_p}\right)^2\right] + \frac{\alpha_e}{2\tau_p} \exp\left[\frac{-|x - \mu_p|}{\tau_p}\right],$$

where  $\alpha_e$  is the fractional exponential component,  $\sigma_p$  is the Gaussian width (corresponding to the position resolution),  $\mu_p$  is the Gaussian shift (corresponding to the position bias) and  $\tau_p$  is the exponential slope (corresponding to the position distributions in tails).

For electrons from the  $^{16}\text{N}$  calibration source, their spatial distribution function  $N_R(x)$  can be described by the position resolution function smeared by the convolution of  $S(x)$  as[?]:

$$N_R(x) = \int_{-\infty}^{+\infty} S(x)R(x_{fit} - x)dx.$$

Since the  $S(x)$  and  $N_R(x)$  are histograms obtained from the data and MC, we calculate by the bin value  $x_i$ :

$$N_R(x_i) = \sum_{x_i=-\infty}^{+\infty} S(x_i)R(x_{fit}^i - x_i).$$

The  $\chi^2$  is calculated by:

$$\chi^2 = \sum_{i=0}^{N_{bins}} \left[ \frac{N_R(x_{fit}^i) - N_R^{fit}(x_{fit}^i)}{\sigma_i} \right]^2,$$

where  $N_R^{fit}$  is a trial fit to the  $N_R$  by tuning the  $\{\alpha_e, \mu_p, \sigma_p, \tau_p\}$  and  $\sigma_i$  is taken as the bin width of the histograms.

By minimizing the  $\chi^2$ , the parameters of the resolution function,  $\{\alpha_e, \mu_p, \sigma_p, \tau_p\}$  and a best  $N_R^{fit}$  are obtained.

Figure ?? shows a comparison of the reconstructed x position of  $^{16}\text{N}$  events between data and MC. The reconstructed position distributions are fitted with  $N_R^{fit}$ .

Table 4.3 summarizes the values of position resolution parameters obtained from data and MC of  $^{16}\text{N}$  calibration runs at the detector center.

Table 4.3: Position resolution parameters for the MP Water Fitter.

SNO+ experiment

## Appendix A

# Details for the MultiPath Fitter

### A.1 Create a Random Vertex

Four random seeds are generated from the uniform distribution function: *RandFlat* in Class Library for High Energy Physics (CLHEP) library.

One random seed is used for generating the time of the vertex:  $t$  is a random variable following a uniform distribution in a range of [100, 300] ns, say,  $t \sim U(100, 300)$ .

Three random seeds are used for generating the position of the trial vertex:  $ran0 \sim U(0, 1)$ ,  $ran1 \sim U(-1, 1)$  and  $ran2Pi \sim U(0, 2\pi)$ .

Let  $r = \sqrt[3]{ran0} * 10000$  mm,  $\phi = ran2Pi$ ,  $\cos \theta = ran1$  and  $\sin \theta = \sqrt{1 - \cos^2 \theta}$ , then the trial position can be built in Cartesian coordinate system:  $\vec{x}_{trial} = (r \sin \theta \cos \phi, r \sin \theta \sin \phi, r \cos \theta)$ . This procedure ensures that a proper random position is generated inside a sphere with a radius of 10 m.

### A.2 Levenberg-Marquardt (MRQ) Method for Minimization[39]

Levenberg-Marquardt method is a common routine for non-linear fitting. Let  $\mathbf{a} = [a_0, a_1, \dots, a_{M-1}]^T$  be an  $M$ -dimensional vector with  $M$  unknown parameters to be fit, for example,  $\mathbf{a}$  is an event vertex with 4 parameters:  $\mathbf{a} = [x, y, z, t]^T$ .

A  $\chi^2$  merit function with the unknown parameter vector  $\mathbf{a}$  can be built and by mini-

mizing the function, the best-fit  $\mathbf{a}$  can be found.

The  $\chi^2(\mathbf{a})$  can be approximately expanded into a quadratic form of Taylor-series:

$$\chi^2(\mathbf{a}) \simeq \gamma - \mathbf{d} \cdot \mathbf{a} + \frac{1}{2} \mathbf{a} \cdot \mathbf{D} \cdot \mathbf{a}, \quad (\text{A.1})$$

where  $\gamma$  is a  $M$ -dimension constant vector around  $\mathbf{a}$ ,  $\mathbf{d}$  is a  $M$ -dimension vector and  $\mathbf{D}$  is a  $M \times M$  Hessian matrix.

To find a  $\mathbf{a}_{min}$  so that a  $\min \chi^2(\mathbf{a}_{min})$  is reached, in computing science we usually use iteration steps:

$$\mathbf{a}_{min} = \mathbf{a}_{cur} + D^{-1}[-\nabla \chi^2(\mathbf{a}_{cur})], \quad (\text{A.2})$$

where  $\mathbf{a}_{cur}$  is the current trial value of  $\mathbf{a}$  and we assume matrix  $\mathbf{D}$  is invertible. The  $\mathbf{a}_{cur}$  thus jumps onto  $\mathbf{a}_{min}$ .

According to the definition of a  $\chi^2$  merit function, it can be written out explicitly as:  $\chi^2(\mathbf{a}) = \sum_{i=0}^{N-1} [\frac{y_i - y(x_i|\mathbf{a})}{\sigma_i}]^2$ , with the same Taylor expansion, the quadratic form is written as:

$$\chi^2(\mathbf{a}) \approx \chi^2(\mathbf{a}_{cur}) + \sum_k \frac{\partial \chi^2(\mathbf{a}_{cur})}{\partial a_k} \delta a_k + \frac{1}{2} \sum_{kl} \frac{\partial^2 \chi^2(\mathbf{a}_{cur})}{\partial a_k \partial a_l} \delta a_k \delta a_l, \quad (\text{A.3})$$

where the first derivatives are:

$$\frac{\partial \chi^2}{\partial a_k} = -2 \sum_{i=0}^{N-1} [\frac{y_i - y(x_i|\mathbf{a})}{\sigma_i}] \frac{\partial y(x_i|\mathbf{a})}{\partial a_k}, k = 0, 1, \dots, M-1, \quad (\text{A.4})$$

and the second derivatives are:

$$\frac{\partial^2 \chi^2}{\partial a_k \partial a_l} = 2 \sum_{i=0}^{N-1} \left\{ \frac{\partial y(x_i|\mathbf{a})}{\partial a_k} \frac{\partial y(x_i|\mathbf{a})}{\partial a_l} - [y_i - y(x_i|\mathbf{a})] \frac{\partial^2 y(x_i|\mathbf{a})}{\partial a_k \partial a_l} \right\}, k = 0, 1, \dots, M-1. \quad (\text{A.5})$$

Let  $\beta_k \equiv -\frac{1}{2} \frac{\partial \chi^2}{\partial a_k}$ ,  $\alpha_{kl} \equiv \frac{1}{2} \frac{\partial^2 \chi^2}{\partial a_k \partial a_l}$ , then the factor of 2 is removed. The  $\alpha_{kl}$  is defined as the curvature matrix and  $\alpha = \frac{1}{2} \mathbf{D}$ , which implies that it is the half of the Hessian matrix.

From A.2, we have:  $D(\mathbf{a}_{min} - \mathbf{a}_{cur}) = [-\nabla \chi^2(\mathbf{a}_{cur})] \implies 2\alpha \delta \mathbf{a} = 2\beta$ . The A.2 is now transformed into a systems of linear equations:

$$\sum_{l=0}^{M-1} \alpha_{kl} \delta a_l = \beta_k, \quad (\text{A.6})$$

where  $\delta a_l$  is a varying amount added to the current value of parameter for the next iteration.

The main task now is to calculate  $\alpha_{kl}$  and  $\beta_k$  and then solve for  $\delta a_l$  in A.6. Once  $\delta a_l$  is solved, we can vary the current trial or approximate values of  $\mathbf{a}_{cur}$  and let it go close to or reach the  $\mathbf{a}_{min}$ .

If we consider the method of steepest descent:  $\mathbf{a}_{next} = \mathbf{a}_{cur} - \text{const} \cdot \nabla \chi^2(\mathbf{a}_{cur})$ , where const is a constant, then the  $\delta a_l$  is solved by

$$\delta a_l = \text{const} \cdot \beta_l, \quad (\text{A.7})$$

where no Hessian matrix is needed.

In the Levenberg-Marquardt method, in order to solve for  $\delta a_l$ , the detailed calculation of  $\mathbf{D}^{-1}$  in A.2 and the simplified calculation of steepest descent in A.7 are combined and a smooth transition between A.2 and A.7 is considered.

In A.7, the const describes the distance or magnitude of how far the parameter should go along the gradient  $\beta_l$ . From dimensional analysis, since  $\beta_k \equiv -\frac{1}{2} \frac{\partial \chi^2}{\partial a_k}$  and  $\chi^2$  is a non-dimensional number,  $[\beta_l] = [1/a_l]$ . Then from A.7,  $[\text{const}] = [a_l^2]$ . The const has the same dimension to the term  $1/\alpha_{ll} = 1/(\frac{1}{2} \frac{\partial^2 \chi^2}{\partial a_l \partial a_l})$ , i.e., the diagonal elements in the curvature matrix. A bridge between A.2 and A.7 is thus built. The diagonal elements in the curvature matrix can control the magnitude of the const, tells how far the parameter should go along the gradient.

Then A.7 can be written as:

$$\delta a_l = \frac{1}{\lambda \alpha_{ll}} \beta_l \text{ or } \lambda \alpha_{ll} \delta a_l = \beta_l, \quad (\text{A.8})$$

where  $\alpha_{ll}$  is written in a form of  $\alpha_{ll} = \sum_{i=0}^{N-1} \frac{1}{\sigma_i^2} \left[ \frac{\partial y(x_i | \mathbf{a})}{\partial a_l} \frac{\partial y(x_i | \mathbf{a})}{\partial a_l} \right]$  to ensure that  $\alpha_{ll}$  is always positive; a fudge factor  $\lambda$  can be set to  $\lambda \gg 1$  to avoid the case when the value of const is taken too large.

Compare A.6 and A.8, if define a new curvature matrix  $\alpha'$  as  $\alpha'_{jj} \equiv (1 + \lambda) \alpha_{jj}$  (for diagonal elements) and  $\alpha'_{jk} \equiv \alpha_{jk}$  ( $j \neq k$ ) (for non-diagonal elements), these two equations can be combined into one:

$$\sum_{l=0}^{M-1} \alpha'_{kl} \delta a_l = \beta_k \quad (\text{A.9})$$

From the definition of  $\alpha'$ , if  $\lambda$  takes a large value,  $\alpha'$  is dominated by diagonal elements, then A.9 is close to A.8; while if  $\lambda \rightarrow 0$ , A.9 is close to A.6.

The algorithm of Levenberg-Marquardt method requires a reasonable start value (first guess) of the fitting parameter  $\mathbf{a}$  and a reasonable preset value of  $\lambda$  (usually take  $\lambda = 0.001$ ). The iteration loop of the algorithm is: calculate the value of  $\chi^2(\mathbf{a})$ , solve for  $\delta\mathbf{a}$  from A.9 and then calculate  $\chi^2(\mathbf{a} + \delta\mathbf{a})$ . During this loop, the algorithm checks whether  $\chi^2(\mathbf{a} + \delta\mathbf{a}) \geq \chi^2(\mathbf{a})$ , if it is,  $\lambda$  is increased by  $\lambda = 10 \cdot \lambda$ ; if not,  $\lambda$  is decreased by  $\lambda = 0.1 \cdot \lambda$ .

The iteration loop is terminated when the change amount of the  $\chi^2$  is negligible: if the loop calculates several  $\chi^2$  values which are close to each other (for example,  $|\chi^2_{current} - \chi^2_{previous}| < 0.001$ ), the algorithm will consider the  $\chi^2$  is minimized with a set of best-fit parameters. Here the termination condition of iterating the  $\chi^2$  value to convergence to machine accuracy or to the roundoff limit is not used, since  $\chi^2$  is a statistical quantity rather than a solution of an equation. It is not statistical meaningful to vary the value of  $\mathbf{a}$  to vary  $\chi^2$  by a small amount  $\ll 1$ .

Once the minimum is reached, set  $\lambda = 0$  and then the estimated covariance matrix of the standard errors in the fitted  $\mathbf{a}$  can be calculated as:  $C \equiv \alpha^{-1}$ .
